AIR GAP INTEGRATION

BACKGROUND OF THE INVENTION

[0001] Low dielectric constant materials are used as interlayer dielectrics in microelectronic devices, such as semiconductor devices, to reduce the resistance-capacitance ("RC") delay and improve device performance. As device sizes continue to shrink, the dielectric constant ("k") of the material between metal lines must also decrease to maintain the improvement. Certain low-k materials have been proposed, including various carbon-containing materials such as organic polymers and carbon-doped oxides. The eventual limit for a dielectric constant is $k = 1$, which is the value for a vacuum. Methods and structures have been proposed to incorporate void spaces or "air gaps" in attempts to obtain dielectric constants closer to $k = 1$. One major issue facing air gap technology is how to remove sacrificial material to facilitate multi-layer structures. Another major issue facing air gap technology is how to facilitate air gap creation while providing a structure which can withstand modern processing steps, such as chemical-mechanical polishing and thermal treatment, as well as post processing mechanical and thermo-mechanical rigors.

BRIEF DESCRIPTION OF THE DRAWINGS

[0002] The present invention is illustrated by way of example and is not limited in the figures of the accompanying drawings, in which like references indicate similar elements. Features shown in the drawings are not intended to be drawn to scale, nor are they intended to be shown in precise positional relationship.

[0003] Figures 1A-1L depict cross-sectional views of various aspects of one embodiment of the present invention.

[0004] Figures 2A-2B depict cross-sectional views of various aspects of one embodiment of the present invention wherein peripheral structural layers are incorporated.

[0005] Figures 3A-3H depict cross-sectional views of various aspects of one embodiment of the present invention wherein a capping layer is incorporated.

DETAILED DESCRIPTION

[0006] In the following detailed description of embodiments of the invention, reference is made to the accompanying drawings in which like references indicate similar elements. The illustrative embodiments described herein are disclosed in sufficient detail to enable those skilled in the art to practice the invention. The following detailed description is therefore not to be taken in a limiting sense, and the scope of the invention is defined only by the appended claims.

[0007] Referring to Figure 1A, a microelectronic structure, such as a semiconductor structure, is depicted having a substrate layer (100) adjacent a dielectric layer (102), which is positioned between an etch stop layer (108) and the substrate layer (100). The dielectric layer (102) and etch stop layer (108) are cross sectionally interrupted by via conductive layers (104, 105) crossing the dielectric layer (102) and etch stop layer (108). Each of the via conductive layers (104, 105) is isolated from the dielectric layer (102) and etch stop layer (108) by a barrier layer (106) which also crosses the dielectric layer (102) and etch stop layer (108). Such a microelectronic structure may be recognizable as the bottom portion of a conventional semiconductor interconnect integration.

[0008] The substrate layer (100) may comprise any surface generated when making an integrated circuit, upon which a conductive layer may be formed. Substrate (100) thus may comprise, for example, active and passive devices that are formed on a silicon wafer, such as transistors, capacitors, resistors, diffused junctions, gate electrodes, local interconnects, etcetera. Substrate (100) may also comprise insulating materials (e.g., silicon dioxide, either undoped or doped with phosphorus or boron and phosphorus; silicon nitride; silicon oxynitride; or a polymer) that separate active and passive devices from the conductive layer or layers that are formed adjacent them, and may comprise other previously formed conductive layers.

[0009] The etch stop layer (108) preferably comprises a material, such as silicon nitride or another known etch stop material appropriately matched with the etchability of adjacent layers, which

selectively does not substantially etch when the layer above (110 in Figure 1B, for example) is being etched. The etch stop layer (108) may be deposited using conventional chemical vapor deposition (“CVD”), plasma enhanced CVD (“PECVD”), or low-pressure CVD techniques, as are well known in the art, at a thickness preferably between about 10 nanometers and about 200 nanometers.

[0010] The barrier (106) and via conductive (104, 105) layers may be formed using conventional patterning, trenching, barrier deposition, and conductive material deposition techniques, as would be apparent to one skilled in the art. In one embodiment, for example, subsequent to patterning and trenching, a thin barrier layer (106) is deposited using conventional techniques such as CVD or PECVD, after which conductive material is deposited using electroplating techniques. The via conductive layers (104, 105) preferably comprise a highly conductive material, such as tungsten or copper or other conventionally utilized interconnect conductive materials, and the barrier layer (106) comprises a material such as silicon carbide, tantalum nitride, or titanium nitride which is appropriately matched with the selected conductive material for the via conductive layers (104, 105), as would be apparent to one skilled in the art.

[0011] Referring to Figure 1B, subsequent to formation of the structures depicted in Figure 1A, a sacrificial dielectric layer (110) may be deposited. The sacrificial dielectric layer (110) preferably comprises silicon dioxide, silicon oxynitride, silicon oxyfluoride, or a polymeric dielectric material. Suitable polymeric dielectric materials for the sacrificial dielectric layer (110) include but are not limited to polynorbornene-based polymers, such as that sold under the trade name “Unity400TM”, distributed by Promerus LLC; polycyclohexene; the co-polymer of polypropylene oxide and polyethylene oxide; polystyrene; poly(p-phenylene); polyxylene; cross-linked polymethylmethacrylate (“PMMA”); polyarylene-based polymeric dielectrics such as that sold under the trade name “SiLKTM”, distributed by Dow Chemical Corporation; poly(aryl ether)-based polymeric dielectrics such as that sold under the trade name “FLARETM”, distributed by Honeywell

Corporation; and polyarylene-based spin-on dielectrics such as that sold under the trade name "GX-3TM", also from Honeywell Corporation. Depending upon the material selected for this and other associated layers, such as the conductive layer (142) discussed below in reference to Figure 1H, the sacrificial dielectric layer (110) may be deposited using conventional techniques, such as spin-on, chemical vapor deposition ("CVD"), plasma-enhanced chemical vapor deposition ("PECVD"), evaporative deposition, or physical vapor deposition ("PVD") to form a layer having a thickness between about 200 nanometers and about 1,500 nanometers. In the case of spin-on or other deposition techniques, solvent may need to be removed by evaporative techniques familiar to those skilled in the art.

[0012] Referring to Figure 1C, conventional patterning and etching techniques may be utilized to form trenches (112, 113) which subdivide the sacrificial dielectric material into distinct sacrificial layer portions (150, 152, 154), as depicted in the cross sectional view of Figure 1C. Subsequent to formation of the trenches (112, 113), an etch stop layer (114) is deposited, as shown in Figure 1D. The etch stop layer (114) provides a similar function as the previously described etch stop layer (108), and may comprise a similar material. For example, the etch stop layer (114) may comprise silicon nitride, deposited using conventional conformal CVD or PECVD techniques.

[0013] Referring to Figure 1E, a structure similar to that of Figure 1D is depicted, with the exception that a photoresist layer (116) has been deposited adjacent the etch stop (114) layer. The photoresist layer (116) preferably comprises a conventional polymeric photoresist material, such as those based upon the poly(norbornene) polymeric backbone with photoactive sidegroups, which may be deposited as depicted using spin-on techniques. Referring to Figure 1F, the photoresist layer of Figure 1E (116) may be converted to a patterned photoresist layer (118) using conventional techniques to facilitate removal of targeted portions (120, 122, 124, 126, 128) of the etch stop layer (114). Referring to Figure 1G, subsequent to etching and removal of the patterned photoresist layer

(118), barrier layers (138, 140) are formed adjacent the remaining etch stop layer portions (130, 132, 134, 136) and via conductive layers (104, 105). These barrier layers (138, 140) may comprise a conventional barrier material associated with the material selected for the subsequently deposited conductive layer (142), as depicted in Figure 1H. In one embodiment, for example, the conductive layer (142) comprises copper, deposited using conventional electroplating techniques, and the barrier layers (138, 140) comprise tantalum nitride, titanium nitride, or other barrier or shunt materials conventionally paired with copper, such as cobalt, to isolate the copper from adjacent dielectric materials, deposited using conventional techniques such as CVD or PECVD.

[0014] Referring to Figure 1I, subsequent to a planarization treatment such as chemical mechanical planarization, distinct conductive layers (144, 146) are formed between the sacrificial dielectric layer portions (150, 152, 154). As shown in Figure 1J, a protective layer (194) may then be formed adjacent the planarized surface and patterned to leave behind discrete portions (196, 198) of the protective layer (194). Referring to Figure 1K, the discrete portions (196, 198) depicted in Figure 1J have been patterned to provide protection of the underlying conductive layers (144, 146). The result of forming discrete conductive layers (144, 146) into sacrificial dielectric layer portions (150, 152, 154), as described above in reference to Figures 1B-1K, may be referred to as forming an interconnect sublayer (230), upon which other layers, such as other interconnect sublayers, or protective layers (196, 198) may be formed. Referring to Figure 1L, the sacrificial dielectric layer portions (150, 152, 154) previously depicted in Figure 1K have been decomposed and removed to leave behind voids, or "air gaps" (160, 162, 164), between the conductive layers (144, 146). The conversion from a structure similar to that of Figure 1K, to one similar to that of Figure 1L, preferably is accomplished as a two phase treatment comprising decomposing the sacrificial material comprising the sacrificial dielectric layer portions (150, 152, 154) to form a decomposition, and removing the decomposition to leave behind air gaps. Preferably the sacrificial material is

decomposed by applying a wet etchant, such as hydrofluoric acid, to selectively decompose, or dissolve, the sacrificial dielectric material without significantly damaging other associated structures, such as the etch stop layers (108, 130, 132, 134, 136). Sacrificial materials may also be selectively decomposed or dissolved using thermal or thermochemical techniques utilizing energy from heat, plasma, or both. Removing the decomposition preferably is accomplished by introducing a conventional water rinse, or by introducing a carrier plasma, such as an oxygen, hydrogen, or nitrogen rich plasma, as would be apparent to one skilled in the art. As depicted in Figure 1L, the decomposition preferably is removed along the removal pathways (240, 242, 244) away from the substrate (100) to leave air gaps or voids (160, 162, 164) behind.

[0015] Such techniques and structures may be applied to form multi-level air gap integrations. For example, referring to Figure 2A, a multi-level integration is depicted wherein conductive, or

"metalization" in the case of metal conductive materials, layers such as those depicted in Figure 1L (144, 146) are formed using various phases of patterning and electroplating or similar techniques to

reside in vertical stacks, or conductive vertical series (145, 147, 148, 149), as shown in Figure 2A, each conductive vertical series (145, 147, 148, 149) being isolated from others by intact sacrificial

layer portions (150, 152, 154, 156, 158). Referring to Figure 2A, several interconnect sublayers,

such as between about 2 and about 6 sublayers, are stacked to collectively form a multi-layer

interconnect (232). Each of the sublayers may be similar to those described, for example, in

reference to a single interconnect sublayer (230) in Figure 1K. Subsequent to formation of a

structure comprising conductive vertical series (145, 147, 148, 149) separated by intact sacrificial dielectric layer portions (150, 152, 154, 156, 158) as depicted in Figure 2A, the sacrificial dielectric

layer portions (150, 152, 154, 156, 158) may be decomposed and removed along the depicted

removal pathways (240, 242, 244, 246, 248), as depicted in Figure 2B, to leave behind voids or air

gaps (160, 162, 164, 166, 168). Side walls of the conductive vertical series (145, 147, 148, 149)

define the air gaps (160, 162, 164, 166, 168) between the conductive vertical series (145, 147, 148, 149). In various embodiments, the side walls of the conductive vertical series (145, 147, 148, 149) may be the boundary of the conductive layers or the boundary of etch stop (130, 132, 134, 136) or barrier (138, 140) layers coating the conductive layers of the conductive vertical series (145, 147, 148, 149).

[0016] Referring to Figure 3A, a structure similar to that of Figure 2A is depicted with the exception that peripheral structural layers (170, 172) have been formed on either side of the depicted cross section. The peripheral structural layers (170, 172) preferably comprise a dielectric material with a Young's modulus higher than about 50Gpa to resist bending and deformation. They may be formed using successive sublayer deposition, as with the interconnect sublayers (230) depicted in Figures 1I-1K. In other words, subsequent to each deposition of a sublayer of sacrificial dielectric material, trenches may be formed for both conductive layers and peripheral structural sublayers. Preferred materials for the peripheral structural layers (170, 172) include but are not limited to silicon dioxide and silicon nitride, deposited using conventional techniques such as CVD or PECVD. The accumulation of interconnect sublayers buttressed by peripheral structural sublayers, followed by formation of a protective layer (194) may form a structure such as that depicted in Figure 3A. As shown in Figure 3A, the peripheral structural layers (170, 172) may be formed to protrude slightly more from the plane of the substrate layer (100) than the uppermost surfaces of the sacrificial dielectric layer portions (150, 152, 154, 156, 158) to facilitate a relatively planar surface (210) subsequent to forming the protective layer (194) between the two peripheral structural layers (170, 172).

[0017] Referring to Figure 3B, in a manner similar to that described in reference to Figure 1L and 2B, the depicted structure may result from patterning the protective layer (194) of Figure 3A into discrete protective layer portions (196, 198, 200, 202) adjacent the depicted conductive vertical

series (145, 147, 148, 149), decomposing portions of the sacrificial dielectric layer portions (150, 152, 154, 156, 158), and removing the decomposition using the disclosed techniques. Throughout the decomposing the removing treatments, the conductive vertical series (145, 147, 148, 149) remain isolated from associated chemistries by the sacrificial dielectric layer portions (150, 152, 154, 156, 158) and the remaining portions of previously deposited etch stop and barrier layers, similar to those depicted in Figure 1G (130, 138). The decomposition preferably is removed away from the direction of the substrate layer (100) along the depicted pathways (240, 242, 244, 246, 248) to leave behind air gaps or voids (160, 162, 164, 166, 168).

[0018] Subsequent to removal of the sacrificial material, a structure such as that depicted in Figure 3B may be somewhat unstable in terms of its ability to withstand loads and resist unwanted deflection. In particular, each of the conductive vertical series (145, 147, 148, 149) may susceptible to undesirable levels of cantilever bending during subsequent process treatments such as chemical mechanical polishing upon subsequently formed layers. To bolster the structure, and also to prevent introduction of subsequently deposited materials into the air gaps (160, 162, 164, 166, 168), one or more capping layers may be added.

[0019] Referring to Figure 3C, one embodiment incorporates a first capping layer (180) comprising a relatively low Young's modulus polymeric material, such as polyimide or a packaging polymeric material such as a benzocyclobutene-based polymer material, sold, for example, under the tradename "Cyclotene™" by Dow Chemical Corporation, stretched over and adhered to the uppermost surfaces of the structure, namely the peripheral structural layers (170, 172) and uppermost surfaces of the discrete protective layer portions (196, 198, 200, 202) adjacent the depicted conductive vertical series (145, 147, 148, 149). The first capping layer (180) material is placed under a tensile load (184) and coated with an adhesion promoter (188) such as hexamethyldisiloxane (HDMS) before it is positioned adjacent such surfaces. Referring to Figure 3D, the first capping layer (180) may be

pushed into place using a highly distributed load (186), such as a series of fluid or air jets. Such techniques are conventionally utilized in the preparation of thin film masks for semiconductor processing. A resultant depiction of such positioning with this embodiment is shown in Figure 3E. The first capping layer (180) as depicted in this embodiment preferably has a thickness between about 5 and about 25 microns. A conventional heating process may be utilized to evacuate solvents and cure polymer materials.

[0020] Referring to Figure 3F, additional capping layers may be added for added structural rigidity and potential contact formation. In the depicted embodiment, a second capping layer (190) is formed adjacent the first capping layer (180), the second capping layer preferably having a Young's modulus greater than about 50GPa and comprising a material such as silicon nitride or silicon dioxide deposited at a thickness of around 2 microns using conventional techniques such as CVD or PECVD. Subsequent to formation of the second capping layer (190), a third capping layer (212) is

may also be formed for added protection. In the depicted embodiment, the third capping layer (212) comprises another layer of polymeric material similar to the first capping layer, formed using similar techniques.

[0021] Referring to Figures 3F, 3G, and 3H, the three capping layers (180, 190, 212) may be utilized to facilitate formation and support of a contact, such as a conventional C4 contact. As shown in Figure 3G, the three capping layers (180, 190, 212) and underlying protective layer portions shown intact in Figure 3F (196, 198, 200, 202) may be patterned using conventional techniques to gain access to the underlying conductive materials. Subsequently, C4 or similar contacts (222, 224, 226, 228) may be formed using conventional techniques, such as patterning and electroplating subsequent to appropriate under-ball-metallurgy deposition, as would be apparent to one skilled in the art.

[0022] Thus, a novel microelectronic integration solution is disclosed. Although the invention is described herein with reference to specific embodiments, many modifications therein will readily

occur to those of ordinary skill in the art. Further, the foregoing description of embodiments of the invention and the claims following include terms, such as left, right, over, under, upper, lower, first, second, etc. that are used for descriptive purposes only and are not to be construed as limiting. The embodiments of a device or article described herein can be manufactured, used, or shipped in a number of positions and orientations. Accordingly, all such variations and modifications are included within the intended scope of the invention as defined by the following claims.
